Barrierefreier Zugang: Boltzmanngasse 5, Lift, 1. Stock rechts über den Gang zum Hintereingang des Hörsaals

Abstract:

Diffusion and ionic transport in solids, lithium compounds in particular, presently attracts great interest with respect to applications, e.g. Li ion batteries, as well as concomitant basic research being in the focus of the present talk.

One of the most versatile experimental methods to gain detailed insights into atomic/ionic diffusion in solids is nuclear magnetic resonance (NMR) utilizing spin bearing nuclei, inherent or introduced in the sample, as ‘internal spies’. An arsenal of various NMR techniques gives access to jump rates over more than ten decades and the corresponding activation barriers. Information on the jump geometry may be obtained as well. Combining NMR results with those of other microscopic and macroscopic diffusion methods, such as ac and dc ionic conductivity and mass tracer measurements, and comparing solids in different structural forms yields additional insights, e.g., into diffusion mechanisms. Recent examples of diffusion studies in different materials classes deal in particular with crystalline, nanocrystalline, nanoglassy and glassy Li ion conductors.
